

MINISTRY OF HEALTH OF THE REPUBLIC OF BELARUS

INSTRUCTION  
for Medical Use of Pharmaceutical Product

VANCOMYCIN-TF  
powder for solution for infusion 500 mg, 1000 mg

Stamp: [APPROVED  
by the MINISTRY OF HEALTH  
OF THE REPUBLIC OF BELARUS  
Order of the Ministry of Health  
of the Republic of Belarus  
No. 700 dd. 06.07.2020]

**Trade name** Vancomycin-TF.

**International non-proprietary name** Vancomycin.

**Pharmaceutical form** Powder for solution for infusion 500 mg, 1000 mg.

**Description** White or almost white powder. Hygroscopic.

**Composition per 1 vial**

Vancomycin (as vancomycin hydrochloride) – 500 mg which is equivalent to not less than 500 000 IU vancomycin.

Vancomycin (as vancomycin hydrochloride) – 1000 mg which is equivalent to not less than 1 000 000 IU vancomycin.

**Pharmacotherapeutic group** Antibacterials for systemic use. Glycopeptide antibacterials.

**ATC code:** J01XA01.

**Pharmacological properties:**

*Pharmacodynamics*

*Mechanism of action*

Vancomycin is a tricyclic glycopeptide antibiotic that inhibits the synthesis of the cell wall of sensitive bacteria by binding with high affinity to the D-alanyl-D-alanine terminus of cell wall precursor units. The medicinal product is slowly bactericidal for dividing microorganisms. In addition, it impairs the permeability of the bacterial cell membrane and RNA synthesis.

*Pharmacokinetic/Pharmacodynamic relationship (PK/PD)*

Vancomycin displays concentration-independent activity with the area under the concentration curve (AUC) divided by the minimum inhibitory concentration (MIC) of the target organism as the primary predictive parameter for efficacy. On basis of *in vitro*, animal and limited human data, an AUC/MIC ratio of 400 has been established as a PK/PD target to achieve clinical effectiveness with vancomycin. To achieve this target when MICs are  $\geq 1.0$  mg/l, dosing in the upper range and high trough serum concentrations (15-20 mg/l) are required.

*Mechanism of resistance*

Acquired resistance to glycopeptides is most common in enterococci and is based on acquisition of various van gene complexes which modifies the D-alanyl-D-alanine target to D-alanyl-D-lactate or D-alanyl-D-serine which bind vancomycin poorly. In some countries, increasing cases of resistance are observed particularly in enterococci; multi-resistant strains of *Enterococcus faecium* are especially alarming.

Van genes have rarely been found in *Staphylococcus aureus*, where changes in cell wall structure result in “intermediate” susceptibility, which is most commonly heterogeneous. Also, methicillin-resistant *staphylococcus* strains (MRSA) with reduced susceptibility for vancomycin were reported. The reduced susceptibility or resistance to vancomycin in *Staphylococcus* is not well understood.

There is no cross-resistance between vancomycin and other classes of antibiotics. Cross resistance with other glycopeptide antibiotics, such as teicoplanin, does occur. Secondary development of resistance during therapy is rare.

*Synergetic action*

The combination of vancomycin with an aminoglycoside antibiotic has a synergistic effect against many strains of *Staphylococcus aureus*, non-enterococcal group D-streptococci, enterococci and streptococci of the *Viridans* group. The combination of vancomycin with a cephalosporin has a synergistic effect against some oxacillin-resistant *Staphylococcus epidermidis* strains, and the combination of vancomycin with rifampicin has a synergistic effect against *Staphylococcus epidermidis* and a partial synergistic effect against some *Staphylococcus aureus* strains.

As vancomycin in combination with a cephalosporin may also have an antagonistic effect against some *Staphylococcus epidermidis* strains and in combination with rifampicin against some *Staphylococcus aureus* strains, preceding synergism testing is useful.

Specimens for bacterial cultures should be obtained in order to isolate and identify the causative organisms and to determine their susceptibility to vancomycin.

#### *Susceptibility testing breakpoints*

Vancomycin is active against gram-positive bacteria, such as staphylococci, streptococci, enterococci, pneumococci, and clostridia. Gram-negative bacteria are vancomycin-resistant. The prevalence of acquired resistance may vary geographically and with time for selected species and local information on resistance is desirable, particularly when treating severe infections. As necessary, expert advice should be sought when the local prevalence of resistance is such that the utility of the agent in at least some types of infections is questionable.

Minimum inhibitory concentration (MIC) breakpoints established by the European Committee on Antimicrobial Susceptibility Testing (EUCAST)\* are as follows:

Microorganisms	Susceptible	Resistant
<i>Staphylococcus aureus</i> <sup>1</sup>	≤2 mg/L	>2 mg/L
Coagulase-negative staphylococci <sup>1</sup>	≤4 mg/L	>4 mg/L
<i>Enterococcus</i> spp.	≤4 mg/L	>4 mg/L
<i>Streptococcus</i> groups A, B, C, and G	≤2 mg/L	>2 mg/L
<i>Streptococcus pneumoniae</i>	≤2 mg/L	>2 mg/L
Gram-positive anaerobes	≤2 mg/L	>2 mg/L

<sup>1</sup> *S. aureus* with vancomycin MIC values of 2 mg/L are on the border of the wild type distribution and there may be an impaired clinical response.

Gram-positive microorganisms are sensitive to vancomycin including *Enterococcus faecalis*, *Staphylococcus aureus*, methicillin-resistant *Staphylococcus aureus*, coagulase-negative *Staphylococci*, *Streptococcus* spp., *Streptococcus pneumoniae*, *Enterococcus* spp.; anaerobic species: *Clostridium* spp., except *Clostridium innocuum*, *Eubacterium* spp., *Peptostreptococcus* spp. Acquired resistance is possible for *Enterococcus faecium*.

Inherently resistant microorganisms: all gram-negative bacteria, gram-positive aerobic species including *Erysipelothrix rhusiopathiae*, heterofermentative *Lactobacillus*, *Leuconostoc* spp., *Pediococcus* spp., anaerobic species: *Clostridium innocuum*.

#### **Pharmacokinetics**

##### *Absorption*

Vancomycin is administered intravenously for the treatment of systemic infections.

In the case of patients with normal renal function, intravenous infusion of multiple doses of 1g vancomycin (15 mg/kg) for 60 minutes produces approximate average plasma concentrations of 50-60 mg/L, 20-25 mg/L and 5-10 mg/L, immediately, 2 hours and 11 hours after completing the infusion, respectively. The plasma levels obtained after multiple doses are similar to those achieved after a single dose.

Vancomycin is not usually absorbed into the blood after oral administration. However, absorption may occur after oral administration in patients with (pseudomembranous) colitis. This may lead to vancomycin accumulation in patients with co-existing renal impairment.

\*EUCAST Breakpoints (version 9.0, 01.01.2019).

### *Distribution*

The volume of distribution is about 60 L/1.73 m<sup>2</sup> body surface. At serum concentrations of vancomycin of 10 mg/l to 100 mg/l, the binding of the medicinal product to plasma proteins is approximately 30-55%, measured by ultra-filtration.

Vancomycin diffuses readily across the placenta and is distributed into cord blood. In non-inflamed meninges, vancomycin passes the blood-brain barrier only to a low extent.

### *Metabolism and elimination*

There is very little metabolism of the medicinal product. After parenteral administration approximately 75-90% of medicinal product is excreted within 24 hours through glomerular filtration via the kidneys.

The elimination half-life of vancomycin is 4 to 6 hours in patients with normal renal function and 2.2-3 hours in children. Plasma clearance is about 0.058 L/kg/h and kidney clearance is about 0.048 L/kg/h. In the first 24 hours, approximately 80% of an administered dose of vancomycin is excreted in the urine through glomerular filtration. Renal dysfunction delays the excretion of vancomycin. In anephric patients, the mean half-life is 7.5 days. Due to ototoxicity of vancomycin therapy-adjunct monitoring of the plasma concentrations is indicated in such cases.

Biliary excretion is insignificant (less than 5% of a dose).

Although the vancomycin is not eliminated efficiently by haemodialysis or peritoneal dialysis, there have been reports of an increase in vancomycin clearance with haemoperfusion and haemofiltration.

After oral administration, only a fraction of the administered dose is recovered in the urine. In contrast, high concentrations of vancomycin are found in the faeces (>3100 mg/kg with doses of 2 g/day).

### *Linearity*

Vancomycin concentration generally increases proportionally with increasing dose. Plasma concentrations during multiple dose administration are similar to those after the administration of a single dose.

### *Pharmacokinetics in specific groups*

Vancomycin is primarily cleared by glomerular filtration. In patients with *impaired renal function* the terminal elimination half-life of vancomycin is prolonged and the total body clearance is reduced.

Vancomycin pharmacokinetics is not altered in patients *with hepatic impairment*.

Significantly increased doses may be required to achieve therapeutic serum concentrations in *pregnant women*.

Vancomycin distribution may be altered in overweight patients due to increases in volume of distribution, in renal clearance and possible changes in plasma protein binding. In these subpopulations vancomycin serum concentrations were found higher than expected in male healthy adults.

### *Pediatric population*

Pharmacokinetics of vancomycin has shown wide inter-individual variability in preterm and term *neonates*. In neonates, after intravenous administration, vancomycin volume of distribution varies between 0.38 and 0.97 L/kg, similar to adult values, while clearance varies between 0.63 and 1.4 ml/kg/min. Half-life varies between 3.5 and 10 h, reflecting the usual lower clearance values in neonates.

In infants and older children, the volume of distribution ranges between 0.26-1.05 L/kg while clearance varies between 0.33-1.87 ml/kg/min.

### **Preclinical safety data**

Although no long-term studies in animals have been performed to evaluate carcinogenic potential, no mutagenic potential of vancomycin was found in standard laboratory tests. No definitive fertility studies have been performed.

### **Therapeutic indications:**

Vancomycin-TF is indicated in all ages group for treatment of the following infections:

- complicated skin and soft tissue infections;

- bone and joint infections;
- community-acquired pneumonia;
- hospital-acquired pneumonia (including ventilator-associated pneumonia);
- infective endocarditis;

Vancomycin is also indicated in all age groups for the perioperative antibacterial prophylaxis in patients that are at high risk of developing bacterial endocarditis when undergoing major surgical procedures.

#### Oral administration

Vancomycin-TF is indicated in all age groups for the treatment of *Clostridium difficile* infection (CDI).

Consideration should be given to official guidance on the appropriate use of antibacterial agents.

#### **Contraindications**

Hypersensitivity to the active substance.

*Vancomycin-TF should not be administered intramuscularly due to the risk of necrosis at the site of administration!*

#### **Special warnings and precautions for use**

##### *Usage in pregnancy and breastfeeding*

Teratology studies have been performed at 5 times the human dose in rats and 3 times the human dose in rabbits, and have revealed no evidence of harm to the foetus due to vancomycin. In a controlled clinical study, the potential ototoxic and nephrotoxic effects of vancomycin hydrochloride on infants were evaluated when the medicinal product was administered to pregnant women for serious staphylococcal infections complicating intravenous drug abuse. Vancomycin hydrochloride was found in cord blood. No sensorineural hearing loss or nephrotoxicity attributable to vancomycin was noted. Because vancomycin was administered only in the second and third trimesters, it is not known whether it causes foetal harm. Vancomycin-TF should be given in pregnancy only if clearly needed and blood levels should be monitored carefully to minimize the risk of foetal toxicity. It has been reported, however, that pregnant patients may require significantly increased doses of vancomycin to achieve therapeutic serum concentrations.

Vancomycin hydrochloride is excreted in human milk. Caution should be exercised when vancomycin is administered to a *nursing woman*. It is unlikely that a nursing infant can absorb a significant amount of vancomycin from its gastro-intestinal tract. Vancomycin-TF should be cautiously given to breast-feeding mothers because of potential adverse reactions in the infant (disturbances in the intestinal flora with diarrhoea, colonisation with yeast-like fungi and possibly sensibilisation). Considering the importance of this medicine for nursing mother, the decision to stop breastfeeding should be considered.

##### *Effects on ability to drive and use machines*

The effect of vancomycin on the ability to drive vehicles and operate mechanisms has not been identified.

##### *Warnings*

##### *Intravenous administration*

Vancomycin-TF is recommended for use only in a clinical settings. Due to injection soreness and site possible tissue necrosis, *Vancomycin-TF must not be administered intramuscularly and by intravenous bolus!*

##### *Hypersensitivity reactions*

When using Vancomycin-TF, serious and occasionally fatal hypersensitivity reactions are possible. In case of hypersensitivity reactions, treatment with vancomycin must be discontinued immediately and the adequate emergency measures must be initiated.

In patients receiving vancomycin over a longer-term period or concurrently with other medications which may cause neutropenia or agranulocytosis, the leukocyte count should be monitored at regular intervals. All patients receiving Vancomycin-TF should have periodic haematologic studies, urine analysis, liver and renal function tests.

Vancomycin-TF should be used with caution in patients with allergic reactions to teicoplanin, since cross hypersensitivity, including fatal anaphylactic shock, may occur.

#### *Spectrum of antibacterial activity*

Vancomycin-TF has a spectrum of antibacterial activity limited to Gram-positive organisms. It is not suitable for use as a single agent for the treatment of some types of infections unless the pathogen is already documented and known to be susceptible or there is a high suspicion that the most likely pathogen(s) would be suitable for treatment with vancomycin.

The rational use of Vancomycin-TF should take into account the bacterial spectrum of activity, the safety profile and the suitability of standard antibacterial therapy to treat the individual patient.

#### *Ototoxicity*

Ototoxicity, which may be transitory or permanent has been reported in patients with prior deafness, who have received excessive intravenous doses, or who receive concomitant treatment with another ototoxic active substance such as an aminoglycoside. Vancomycin-TF should also be avoided in patients with previous hearing loss. Deafness may be preceded by tinnitus. To reduce the risk of ototoxicity, vancomycin blood levels should be determined periodically and periodic testing of auditory function is recommended.

The elderly are particularly susceptible to auditory damage. Monitoring of vestibular and auditory function in the elderly should be carried out during and after treatment. Concurrent or sequential use of other ototoxic substances should be avoided.

#### *Infusion-related reactions*

Rapid bolus administration (i.e. over several minutes) may be associated with exaggerated hypotension (including shock and, rarely, cardiac arrest), histamine-like responses and maculopapular or erythematous rash (“red man's syndrome” or “red neck syndrome”). Vancomycin-TF should be infused slowly in a dilute solution (2.5 to 5.0 mg/ml) at a rate no greater than 10 mg/min and over a period not less than 60 minutes to avoid rapid infusion-related reactions. Stopping the infusion usually results in a prompt cessation of these reactions.

The frequency of infusion-related reactions (hypotension, flushing, erythema, urticaria and pruritus) increases with the concomitant administration of anaesthetic agents. This may be reduced by administering vancomycin by infusion over at least 60 minutes, before anaesthetic induction.

#### *Severe bullous reactions*

Stevens-Johnson syndrome (SJS) has been reported with the use of vancomycin. If symptoms or signs of SJS (e.g. progressive skin rash often with blisters or mucosal lesions) are present, treatment with Vancomycin-TF should be discontinued immediately and specialized dermatological assessment be sought.

#### *Administration site related reactions*

Pain and thrombophlebitis may occur in many patients receiving intravenous vancomycin and are occasionally severe. The frequency and severity of thrombophlebitis can be minimized by administering the medicinal product slowly as a dilute solution and by changing the sites of infusion regularly.

The efficacy and safety of vancomycin has not been established for the intrathecal, intralumbar and intraventricular routes of administration.

*Vancomycin-TF must not be administered intramuscularly due to the risks of necrosis at the site of administration!*

#### *Nephrotoxicity*

Vancomycin-TF should be used with caution in patients with renal failure including anuria, as the possibility of developing toxic effects is much higher in the presence of prolonged high blood concentrations. The risk of toxicity is increased by high blood concentrations and prolonged therapy.

Regular monitoring of blood levels of vancomycin is indicated in high dose therapy and longer-term use, particularly in patients with renal dysfunction or impaired faculty of hearing, as well as in concurrent administration of nephrotoxic or ototoxic substances, respectively.

### *Paediatric population*

The safety of high vancomycin levels in children has not been well studied. The current intravenous dosing recommendations for the paediatric population, in particular for children below 12 years of age, may lead to sub-therapeutic vancomycin levels in a substantial number of children. However, the safety of increased vancomycin dosing has not been properly assessed and doses higher than 60 mg/kg/day cannot be generally recommended.

Vancomycin-TF should be used with caution in premature neonates and young infants due to their renal immaturity and the possible increase in the serum concentration of vancomycin. The blood concentrations of vancomycin should therefore be monitored carefully in these children. Concomitant administration of Vancomycin-TF and anesthetics has been associated with erythema and histamine-like flushing in children. Similarly, concomitant use with nephrotoxic agents such as aminoglycoside antibiotics, non-steroid anti-inflammatory medicinal products (e.g. ibuprofen) and amphotericin B is associated with increased risk of nephrotoxicity and therefore more frequent monitoring of vancomycin serum levels and renal function is indicated.

### *Use in the elderly*

The natural decrement of glomerular filtration with increasing age may lead to elevated vancomycin serum concentrations if dosage is not adjusted (see section “Posology and method of administration”).

### *Drug interactions with anaesthetic agents*

Anaesthetic induced myocardial depression may be enhanced by vancomycin. During anaesthesia, doses must be well diluted and administered slowly with close cardiac monitoring. Position changes should be delayed until the infusion is completed to allow for postural adjustment.

### *Pseudomembranous enterocolitis*

In case of severe persistent diarrhea, pseudomembranous enterocolitis that might be life-threatening should be taken into account. Anti-diarrhea medical products must not be given.

### *Superinfection*

Prolonged use of Vancomycin-TF may result in the overgrowth of non-sensitive microorganisms. Careful observation of the patient is essential. If superinfection occurs during treatment, appropriate measures should be taken.

### Oral administration

Vancomycin-TF should be administered orally only to treat pseudomembranous colitis caused by *Clostridium difficile*.

Testing for *Clostridium difficile* colonization or toxin is not recommended in children younger than 1 year due to high rate of asymptomatic colonisation unless severe diarrhoea is present in infants with risk factors for stasis such as Hirschsprung disease, operated anal atresia or other severe motility disorders. Alternative etiologies should always be sought and *Clostridium difficile* enterocolitis be proven.

### *Potential for systemic absorption*

Absorption may be enhanced in patients with inflammatory disorders of the intestinal mucosa or with *Clostridium difficile*-induced pseudomembranous colitis. These patients may be at risk for the development of adverse reactions, especially if there is a concomitant renal impairment. The greater the renal impairment, the greater the risk of developing the adverse reactions associated with the parenteral administration of vancomycin. Monitoring of serum vancomycin concentrations of patients with inflammatory disorders of the intestinal mucosa should be performed.

### *Nephrotoxicity*

Serial monitoring of renal function should be performed when treating patients with underlying renal dysfunction or patients receiving concomitant therapy with an aminoglycoside or other nephrotoxic medicinal products.

### *Ototoxicity*

Serial tests of auditory function may be helpful in order to minimize the risk of ototoxicity in patients with an underlying hearing loss, or who are receiving concomitant therapy with an ototoxic agent such as an aminoglycoside.

*Drug interactions with anti-motility agents and proton pump inhibitors*

Anti-motility agents should be avoided and proton pump inhibitor use should be reconsidered.

*Development of drug-resistant bacteria*

Oral vancomycin use increases the chance of vancomycin-resistant *Enterococci* populations in the gastrointestinal tract. As a consequence, prudent use of oral vancomycin is advised.

**Posology and method of administration**

Where appropriate, Vancomycin-TF should be administered in combination with other antibacterial agents.

*Intravenous administration*

*Vancomycin-TF must not be administered intramuscularly and intravenously (as a bolus)!*

The medicinal product is administered as intermittent intravenous infusions slowly at a rate of not more than 10 mg/min of at least 60-minute duration which is sufficiently diluted (at least 100 ml per 500 mg or at least 200 ml per 1000 mg).

Vancomycin-TF solution concentration should not exceed 5 mg/ml.

*When administered over a shorter period of time or at higher concentrations, there is a risk of severe hypotension and thrombophlebitis. Also, the rapid infusion of vancomycin can cause flushing of the face and upper half of the body and a short-term rash on the neck and shoulders.*

In patients with the limited fluid intake, a solution with the concentration of 500 mg/50 ml or 1000 mg/100 ml can be used, although the risk of adverse infusion-related reactions may be potentiated.

The initial dose should be based on total body weight. Subsequent dose adjustments should be based on serum concentrations to achieve targeted therapeutic concentrations. Renal function must be taken into consideration for subsequent doses and interval of administration.

*Adults, children aged 12 and above*

The recommended dose is 15 to 20 mg/kg of body weight every 8 to 12 h (not to exceed 2 g per dose).

In seriously ill patients, a loading dose of 25-30 mg/kg of body weight can be used to facilitate rapid attainment of target trough serum vancomycin concentration.

*Infants and children aged from 1 month to less than 12 years of age*

The recommended dose is 10 to 15 mg/kg given every 6 hours.

*Term neonates (from birth to 27 days of post-natal age) and preterm neonates (from birth to the expected date of delivery plus 27 days)*

For establishing the dosing regimen for neonates, the advice of a physician experienced in the management of neonates should be sought. One possible way of dosing vancomycin in neonates is illustrated in the following table:

PMA* (weeks)	Dose (mg/kg)	Administration interval (hours)
<29	15	24
29-35	15	12
>35	15	8

\*PMA – post-menstrual age (gestation age at birth plus chronological age).

*Peri-operative prophylaxis of bacterial endocarditis in all age groups*

The recommended dose is an initial dose of 15 mg/kg prior to induction of anaesthesia. Depending on the duration of surgery, a second vancomycin dose may be required.

Suggested *treatment duration* with Vancomycin-TF is shown in table below. In any case, the duration of treatment should be tailored to the type and severity of infection and the individual clinical response.

Indications for use	Treatment duration
Complicated skin and soft tissue infections: - non necrotizing - necrotizing	7 to 14 days 4 to 6 weeks*
Bone and joint infections	4 to 6 weeks**
Community-acquired pneumonia	7 to 14 days
Hospital-acquired pneumonia, including ventilator-associated pneumonia	7 to 14 days
Infective endocarditis	4 to 6 weeks***

\* Continue until further debridement is not necessary, patient has clinically improved, and patient is afebrile for 48 to 72 hours.

\*\*Longer courses of oral suppression treatment with suitable antibiotics should be considered for prosthetic joint infections.

\*\*\* Duration and need for combination therapy is based on valve-type and organism.

### *Elderly*

Lower maintenance doses may be required due to the age-related reduction in renal function.

### *Renal impairment*

In adults and children with renal impairment, consideration should be given to an initial starting dose followed by serum vancomycin trough levels rather than to a scheduled dosing regimen particularly in patients with severe renal impairment or those receiving renal replacement therapy (RRT) due to the many varying factors that may affect vancomycin levels in them.

In patients with mild or moderate renal failure, the starting dose must not be reduced. In patients with severe renal failure, it is preferable to prolong the interval of administration rather than administer lower daily doses.

Appropriate consideration should be given to the concomitant administration of medicinal products that may reduce vancomycin clearance and/or potentiate its undesirable effects.

Vancomycin is poorly dialyzable by intermittent haemodialysis. However, use of high-flux membranes and continuous renal replacement therapy (CRRT) increases vancomycin clearance and generally requires replacement dosing (usually after the haemodialysis session in case of intermittent haemodialysis).

### *Adults*

Dose adjustments in adult patients could be based on glomerular filtration rate estimated (eGFR) by the following formula:

*Men:*  $[\text{Weight (kg)} \times 140 - \text{age (years)}] / 72 \times \text{serum creatinine (mg/dl)}$ .

*Women:*  $0.85 \times [\text{value calculated by the above formula}]$ .

The usual starting dose for adult patients is 15 to 20 mg/kg that could be administered every 24 hours in patients with creatinine clearance between 20 to 49 ml/min. In patients with severe renal impairment (creatinine clearance below 20 ml/min) or those on renal replacement therapy, the appropriate timing and amount of subsequent doses largely depend on the modality of RRT and should be based on serum vancomycin trough levels and on residual renal function (see section "Special warnings and precautions for use"). Depending on the clinical situation, consideration could be given to withhold the next dose while awaiting the results of vancomycin levels.

In the critically ill patient with renal insufficiency, the initial loading dose (25 to 30 mg/kg) should not be reduced.

### *Paediatric population*

Dose adjustments in paediatric patients aged 1 year and older could be based on glomerular filtration rate estimated (eGFR) by the revised Schwartz formula:

$\text{eGFR (mL/min/1.73}^2) = (\text{height (cm)} \times 0.413) / \text{serum creatinine (mg/dl)}$

$\text{eGFR (mL/min/1.73}^2) = (\text{height (cm)} \times 36.2) / \text{serum creatinine (}\mu\text{mol/dl)}$

For neonates and infants below 1 year of age, expert advice should be sought as the revised Schwartz formula is not applicable to them. Orientative dosing recommendations for the paediatric population are shown in table below:

GFR (mL/min/1.73m <sup>2</sup> )	Vancomycin-TF dose	Frequency
50-30	15 mg/kg	12 hourly
29-10	15 mg/kg	24 hourly
<10	10-15 mg/kg	Re-dose based on levels*
Intermittent haemodialysis		
Peritoneal dialysis		
Continuous renal replacement therapy	15 mg/kg	Re-dose based on levels*

\* The appropriate timing and amount of subsequent doses largely depends on the modality of RRT and should be based on serum vancomycin levels obtained prior to dosing and on residual renal function. Depending on the clinical situation, consideration could be given to withhold the next dose while awaiting the results of vancomycin levels.

#### *Hepatic impairment*

Dose adjustment is not necessary.

#### *Usage during pregnancy*

Significantly increased doses may be required to achieve therapeutic serum concentrations in pregnant women (see section “Special warnings and precautions for use”).

#### *Obese patients*

In obese patients, the initial dose should be individually adapted according to total body weight as in non-obese patients.

#### Oral administration

##### *Patients aged 12 years and older*

Vancomycin-TF is administered at a dose of 125 mg every 6 hours for 10 days for the first episode of non-severe pseudomembranous colitis caused by *Clostridium difficile*. In cases of severe and complicated disease, the dose can be increased to 500 mg every 6 hours for 10 days. The maximum daily dose should not exceed 2 g.

In patients with multiple recurrences, consideration may be given to treat the current episode of *Clostridium difficile* infection (CDI) with vancomycin, 125 mg four times daily for 10 days followed by either tapering the dose, i.e., gradually decreasing it until 125 mg per day or a pulse regimen, i.e., 125-500 mg/day every 2-3 days for at least 3 weeks.

##### *Neonates, infants and children less than 12 years old*

The recommended dose of Vancomycin-TF is 10 mg/kg orally every 6 hours for 10 days. The maximum daily dose should not exceed 2 g.

Treatment duration with Vancomycin-TF may need to be tailored to the clinical course of individual patients. Whenever possible the antibacterials suspected to have caused CDI should be discontinued. Adequate replacement of fluid and electrolytes should be ensured.

#### Vancomycin serum concentrations monitoring

The frequency of therapeutic drug monitoring (TDM) needs to be individualized based on the clinical situation and response to treatment, ranging from daily sampling that may be required in some hemodynamically unstable patients to at least once weekly in stable patients showing a treatment response. In patients with normal renal function, the serum concentration of vancomycin should be monitored on the second day of treatment immediately prior to the next dose.

In patients on intermittent haemodialysis, vancomycin levels should be usually obtained before the start of the haemodialysis session.

After oral administration, monitoring of vancomycin serum concentrations in patients with inflammatory intestinal disorders should be performed.

Therapeutic trough (minimum) vancomycin blood levels should normally be 10-20 mg/l, depending on the site of infection and susceptibility of the pathogen. Trough values of

15-20 mg/l are usually recommended by clinical laboratories to better cover susceptible-classified pathogens with MIC  $\geq$ 1 mg/L.

Model-based methods may be useful in the prediction of individual dose requirements to reach an adequate AUC. The model-based approach can be used both in calculating the personalized starting dose and for dose adjustments based on TDM results

### **Preparation of the solution**

#### *Preparation of solution for infusion*

Standard aseptic rules should be considered when preparing Vancomycin-TF solution.

To prepare Vancomycin-TF solution with the concentration of 50 mg/ml, a needed amount of water for injections should be added to the vial (10 ml for vial containing 500 mg, 20 ml for vial containing 1000 mg).

The reconstituted solution is a clear, colorless solution.

The reconstituted solution in the vial retains its physical and chemical stability for 24 hours at a temperature of 2-8°C (refrigerator).

The reconstituted solution is subject to further dilution in 100 ml (for 500 mg) or 200 ml (for 1000 mg) of diluent to obtain concentration not more than 5 mg/ml. Sodium chloride 0.9% solution for injections or 5% glucose solution for injection may be used as a diluent.

The diluted solution is a clear, colorless solution.

The diluted solution retains its physical and chemical stability for 24 hours at a temperature of 2-8°C (refrigerator).

#### *Oral solution preparation*

To prepare a solution for oral administration the recommended dose of Vancomycin-TF should be diluted in 30 ml of water for injection at room temperature. The prepared solution can be administered for drinking or administered to the patient through a tube. Common flavouring syrups may be added to the solution at the time of administration to improve the taste.

The prepared solution for oral administration retains its physical and chemical stability for 96 hours at a temperature of 2-8°C (refrigerator).

From a microbiological point of view, the medicinal product should be used immediately, otherwise the responsibility for the time and conditions of storage during use lies with the consumer.

### **Undesirable effects**

The most common adverse reactions are phlebitis, pseudo-allergic reactions and flushing of the upper body (“red-neck syndrome”) in connection with too rapid intravenous infusion of vancomycin.

The absorption of vancomycin from the gastrointestinal tract is negligible. However, in severe inflammation of the intestinal mucosa, especially in combination with renal insufficiency, adverse reactions that occur when vancomycin is administered parenterally may appear.

The undesirable effects listed below according to system organ classifications and frequency. The following categories are used to define frequency: very common ( $\geq$ 1/10), common ( $\geq$ 1/100,  $<$ 1/10), uncommon ( $\geq$ 1/1,000,  $<$ 1/100), rare ( $\geq$ 1/10,000,  $<$ 1,000), very rare ( $<$ 1/10,000), unknown (cannot be estimated from the available data).

*Blood and lymphatic system disorders:* rare - reversible neutropenia, agranulocytosis, eosinophilia, thrombocytopenia, pancytopenia.

*Immune system disorders:* rare - hypersensitivity reactions, anaphylactic reactions.

*Ear and labyrinth disorders:* uncommon - transitory or permanent hearing loss; rare - vertigo, tinnitus, dizziness.

*Cardiac disorders:* very rare - cardiac arrest.

*Vascular disorders:* common - decrease in blood pressure; rare - vasculitis.

*Respiratory, thoracic and mediastinal disorders:* common - dyspnoea, stridor.

*Gastrointestinal disorders:* rare - nausea; very rare - pseudomembranous enterocolitis; unknown - vomiting, diarrhea.

*Skin and subcutaneous tissue disorders:* common - flushing of the upper body (“red man syndrome”), exanthema and mucosal inflammation, pruritus, urticaria; very rare - exfoliative

dermatitis, Stevens-Johnson syndrome, Lyell's syndrome, linear IgA bullous dermatosis; unknown - eosinophilia and systemic symptoms (DRESS syndrome), acute generalized exanthematous pustulosis).

*Renal and urinary disorders:* common - renal insufficiency manifested primarily by increased serum creatinine and serum urea; rare - interstitial nephritis, acute renal failure; unknown - acute tubular necrosis.

*General disorders and administration site conditions:* common - phlebitis, redness of the upper body and face; rare - drug fever, shivering, pain and muscle spasm of the chest and back muscles.

#### *Description of selected adverse drug reactions*

Reversible neutropenia usually starts in one week or more after the intravenous therapy or after the total dose of more than 25 g.

During or shortly after rapid infusion anaphylactic/anaphylactoid reactions including wheezing may occur. The reactions abate when administration is stopped, generally between 20 minutes and 2 hours. Vancomycin-TF should be infused slowly.

Tinnitus, possibly preceding onset of deafness, should be regarded as an indication to discontinue treatment.

Ototoxicity has primarily been reported in patients given high doses, or in those on concomitant treatment with other ototoxic medicinal product like aminoglycoside, or in those who had a pre-existing reduction in kidney function or hearing.

If a bullous disorder is suspected, the medicinal product should be discontinued and specialized dermatological assessment should be carried out.

#### *Paediatric population*

The safety profile is generally consistent among children and adult patients. Nephrotoxicity has been described in children, usually in association with other nephrotoxic agents such as aminoglycosides.

#### *Reporting of suspected adverse reactions*

It is important to report suspected adverse reactions after drug product registration in order to ensure continuous monitoring of the benefit-to-risk ratio. Healthcare providers are encouraged to report any suspected adverse drug reactions through national ADR systems.

If any adverse reactions occur, patients are advised to consult a doctor or report adverse reactions to the Adverse Drug Reactions Information Database.

This recommendation applies to any possible adverse reactions, including those not listed in the instructions for medical use, including reports of ineffectiveness of the medicinal product. Adverse reaction reports provide more information on the safety of a medicinal product.

#### **Overdose**

Supportive care is advised, with maintenance of glomerular filtration. Vancomycin is poorly removed from the blood by haemodialysis or peritoneal dialysis. Haemoperfusion with Amberlite resin XAD-4 has been reported to be of limited benefit.

#### **Interactions with other medicinal products**

Concomitant administration of vancomycin and anaesthetic agents has been associated with erythema, histamine-like flushing and anaphylactoid reactions.

There have been reports that the frequency of infusion-related events increases with the concomitant administration of anaesthetic agents. Infusion-related events may be minimized by the administration of vancomycin as a 60-minute infusion prior to anaesthetic induction. When administered during anaesthesia, doses must be diluted to 5 mg/mL or less and administered slowly with close cardiac monitoring. Position changes should be delayed until the infusion is completed to allow for postural adjustment.

Concomitant or sequential systemic or topical use of other potentially nephrotoxic or ototoxic medicinal products, such as amphotericin B, aminoglycosides, bacitracin, polymixin B, colistin, viomycin, cisplatin, loop diuretics and nonsteroidal anti-inflammatory drugs may increase the toxicity of vancomycin and if they need to be concomitantly administered should be used with caution and appropriate monitoring.

With the simultaneous use of vancomycin and muscle relaxants, neuromuscular blockade may develop.

Vancomycin-TF solution has a low pH that may cause physical or chemical instability when it is mixed with other solutions. Mixing with base solutions should be avoided.

Mixtures of solutions of vancomycin and beta-lactam antibiotics have been shown to be physically incompatible. The likelihood of precipitation increases with higher concentrations of vancomycin. It is recommended to adequately flush intravenous lines between administration of these antibiotics. It is also recommended to dilute solutions of vancomycin to 5 mg/mL or less.

*Oral administration:* consideration should be given to discontinuing proton pump inhibitors and anti-motility agents in line with local guidelines for *Clostridium difficile*-infection.

#### **Storage and shelf life**

Keep protected from light at a temperature from 2°C up to 8°C.

Keep out of the reach of children.

Shelf life: 2 years. Do not use after expiration of the shelf life stated on package.

The reconstituted and diluted solutions retain their physical and chemical stability for 24 hours at a temperature of 2-8°C (refrigerator).

The prepared solution for oral administration retains its physical and chemical stability for 96 hours at a temperature of 2-8°C (refrigerator).

#### **Prescription status**

Prescription only medicinal product.

#### **Package**

500 mg in a 10 ml vial for injection or 1000 mg in a 20 ml vial for injection. Vials are corked with rubber stoppers and plugged up by aluminum caps with plastic covers with inscription "FLIP OFF" or without inscription.

5 vials with the instruction for medical use are placed in a cardboard pack.

36 vials for 500 mg or 25 vials for 1000 mg with the instructions for medical use are placed in a cardboard box (package for inpatient hospitals).

#### **Information about manufacturer**

TriplePharm JLLC, 2B Minskaya Str. 223141, Logoysk, Minsk region, Republic of Belarus, tel./fax: (+375) 1774 43 181, e-mail: triplepharm@gmail.com
